

## Metadata Sheet: Ecosystem Impacts from Dams (Indicator No. 7)

Title:	Ecosystem Impacts from Dams
Indicator Number:	7
Thematic Group:	Ecosystems
Rationale:	In addition to core geophysical and chemical indicators of water quantity and quality in international river basins, assessment of ecosystem state is also needed to fully evaluate basin condition. Drinking water quality, sustainable fisheries, and other basin services depend on the collective role of a diverse flora and fauna to maintain ecosystem function. While the aggregate impact of many stressors defines the state of modern river basins, one factor in particular was highlighted in recent work (Vörösmarty et al. 2010) as having a pre-eminent negative impact on aquatic biota: human management of water systems. And, among these management systems impoundment and reservoir operation was emblematic of stresses on aquatic ecosystems and resident biodiversity. The negative impacts on ecosystems of altering waterways through river fragmentation and flow disruption by dams, water transfers and canals must be considered for managing water resources in a sustainable way. It is no longer acceptable to draw water from nature for use in agriculture, industry, and everyday life without taking into account the role that ecosystems play in sustaining a wide array of goods and services, including water supply. Very large dams account for 85 per cent of registered water storage worldwide. In order to compensate for considering only the impacts of very large dams on river fragmentation and flow disruption, dam density has also been factored in this indicator.
Interlinkages:	GW (reduction in mean annual discharge due to impoundments may affect the amount of groundwater recharge), Lakes (reduction in the rate of sedimentation in lakes and reservoirs), LMEs (reduction in the amount of nutrients that reaches marine ecosystems).
Description:	<ul> <li>Three sub- indicators were developed for this indicator to address the various impacts dams can have on ecosystem:</li> <li>a) River Fragmentation (sub-indicator 7a)</li> <li>b) Flow Disruption (sub-indicator 7b)</li> <li>c) Dam Density (sub-indicator 7c)</li> <li>All data are computed in 30' latitude-longitude (i.e., 0.5° degree) gridded format in the geographic projection over the TFDD basin-country-unit (BCU) and transboundary basin regions.</li> </ul>

Computation:	<b><u>1. River Fragmentation (sub-indicator 7a):</u></b> Computed as the River Fragmentation threat driver from Vörösmarty et al. 2010 at 30- minute grid cell resolution. Described as the 'swimmable area' between barriers

	that remains accessible to aquatic species, river fragmentation is a measure of the swimmable distance in any direction from a grid cell to the nearest barrier. The GWSP-GRAND data set of georeferenced large dams was used to define swimmable barriers.						
	<b><u>2. Flow Disruption (sub-indicator 7b):</u></b> Computed as the Flow Disruption threat driver from Vörösmarty et al. 2010 at 30- minute grid cell resolution. Flow disruption was calculated as the magnitude of flow distortion as the residence time of water in large reservoirs.						
	3. Dam Density (sub-indicator 7c): Computed as the Dam Density threat driver from Vörösmarty et al. 2010 at 30-minute grid cell resolution. Dam density represents the density and distribution of very large and medium to large dams mapped at the global scale.						
	<b>Ecosystem Impacts from Dams (Main indicator):</b> Numerical average of the three sub-indicators was calculated at the 30-minute grid cell level then rescaled to fit a 0-1 scale. Average Ecosystem Impacts from Dams over the TFDD BCU and basin regions was calculated as the area-weighted average of the grid cell values within each TFDD BCU and basin. To maintain the integrity of the approach, only results for basins greater than 25,000 – 30,000 km2 can be provided with a scientifically credible level of certainty and thus used in the ranking system. Results for basins smaller than 25,000 – 30,000 km2 have been provided with the tabular information for reference only and were not used in the calculation of rankings						
Units:	See description						
	Due to the standardized nature of the original Vörösmarty et al. 2010 datasets, risk categories were defined as 20% equal-interval classes with the lowest corresponding to very low risk and the highest corresponding to very high risk.
